(a) Technical Field The present invention relates to a method of manufacturing a thin film transistor. (b) Related Art Thin film transistors (TFTs) are generally used to configure driving circuits for active matrix liquid crystal displays or active matrix organic light emitting displays. In recent years, integrated circuit chips that include thin film transistors used for electronic displays have been required to be enlarged or diversified. In addition, the integration of circuits, such as central processing units (CPUs), has been required to be increased. A method of manufacturing an organic semiconductor thin film used for thin film transistors may be classified into a solution process and a deposition process. In a solution process, a solution in which materials, such as small molecules or polymers, are dissolved in solvents is used. The solution process is relatively simple. Also, large area substrates may be easily produced by this process and relatively high throughput may be obtained. However, the thin film fabricated by the solution process is generally applied to a small thin film transistor. In addition, a process of preventing materials from being leaked from a deposited thin film and a process of removing a solvent need to be performed. Further, a process of adding an adhesive has to be performed to adhere the thin film to a substrate. Thus, the process for forming the thin film is complicated. Also, it is difficult to obtain an amorphous thin film. In a deposition process, a thin film is deposited by using a device, such as a chemical vapor deposition (CVD) device or a thermal evaporation device. The thin film is formed by a reaction between a material gas and a heated surface. A method using plasma during a deposition process may be used. Because polycrystalline thin film transistors are formed using the deposition process, a thin film transistor having a high field effect mobility may be fabricated. However, the deposition process is complex. Also, the deposition process has an apparatus to be used as a source, and thus, it may be difficult to find a flexible and inexpensive large area substrate. In addition, although the above-described deposition process is complex, the deposition process is appropriate for forming a device-simulating device, such as a memory array or a liquid crystal display. For example, various features of the deposition process, such as an etch process may be used for forming an electrode, a wire bonding pad and a micro cavity for a laser wavelength. However, in order to mass produce thin
