A novel hexacoordinated polybromide ligand for the efficient photooxidation of water: evidence for the involvement of a hydroxyl radical-like species in the activation of water. We have prepared a new hexacoordinated polybromide ligand, 1,1'-[1,10-Phenanthroline]-3,3'-dibromide, 2-Br-phen, with a bromide at each of its three sites for the photooxidation of water in acetonitrile. The ligand has an unprecedented bridging mode for the bromine atoms, allowing us to examine ligand-substrate interactions of this type. The ligand was found to oxidize water in the presence of dioxygen to form superoxide and hydroxyl radicals, as shown by ESR spectroscopy. The reaction rate increases linearly with the concentration of 2-Br-phen. The ligand oxidizes water 2-3 times faster than the well-known peroxy-ligand, [Ru(bpy)₃](2+), in acetonitrile, indicating that ligand 2-Br-phen is a superior ligand. The large number of oxidizing centers of 2-Br-phen in acetonitrile allows the effective photooxidation of water. The observed rate increases with the concentration of dioxygen, indicating that the ligand is mainly responsible for the photooxidation. In the presence of methyl viologen (MV(2+)) as an electron donor, the radical-generating ability of 2-Br-phen is increased. The reaction rate increases linearly with the concentration of 2-Br-phen, indicating that the electron transfer from the MV(2+) to the ligand is very efficient. Interestingly, the
