Macintosh (USA) Homebrew (macOS) Outlook (Outlook Express; Outlook for Mac; Windows Live Mail). The program can support Unicode, which is the international standard for the representation of characters in computer. Many organizations use directories of users (i.e., membership directories) to store information about members of the organization. For example, organizations that provide access to shared resources may maintain a membership directory to help associate group members with each other and access to the shared resource. Membership directories can be maintained manually using a directory server or via an automated directory service such as a web-based directory service. A directory service may have multiple levels of membership. For example, a directory can be organized into groups (i.e., categories), which in turn can be organized into sub-groups or classes (i.e., categories). Often a user can belong to a group, but not a class within that group. For example, a group within a group can be defined as belonging to the group, but not a class within that group. A user can belong to one or more groups within a directory service. A directory service may include a directory or be used as a component of a directory. Some directory services are single-level (i.e., hierarchical) and some are multi-level (i.e., non-hierarchical). Some directory services have a flat structure (i.e., no directory hierarchy), while others use a tree-like structure (i.e., directories organized into a hierarchy). When constructing a directory of users, security is an important consideration. The accessibility of the directory to a user should be limited such that only a selected group of users are authorized to access particular data stored in the directory. Access can be controlled at the directory level, at the group level, or at the class level. Some directory services allow users to subscribe to a directory to obtain access to that directory. In this way, users can request that their membership to a group or class be added to a directory of that directory. A directory service in which access to directory data is controlled at the group or class level is referred to as a class-based directory service. Examples of class-based directory services include X.500 or LDAP (Lightweight Directory Access Protocol). Some directory services allow directory data to be inherited by a child group if a parent group in which the data belongs is deleted. The child group will remain a member of the parent group but will no longer be able to access data for 6d1f23a050
