jetty allows you to specify the amount of standard processing that will be applied to your web application via the element in the web.xml file.

this allows you to tune the amount of processing that is applied at deployment time. to prevent processing from being applied to your web application at deployment time, it is possible to set the element to null. the webdefault.xml file is named after the webapp and is located in the \$jetty_home/etc/ directory. it is created by jetty, but not configured by jetty. it is meant to be used by webapps that want to customize the server configuration without changing the webapp itself. the file is not looked at by jetty for initial configuration and is not really a part of the server configuration. the main purpose of the webdefault.xml is to expose commonly needed configuration information that would otherwise be buried inside the application's own web-inf/web.xml. in addition to the webdefault.xml file, a module definition can add extra files or a classpath that can be used by a webapp to customize the server configuration. a module definition is located in the \$jetty_home/modules directory. the webdefault.xml.properties file is named after the webapp and is located in the \$jetty_home/etc/ directory. this file is generated by jetty and will be empty unless a webapp is added to the server. this file is used by the webdefault.xml to expose configuration information that would otherwise be buried inside the webapp's own web-inf/web.xml. 5ec8ef588b
